This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.
Highlights

- A model of the robot is essential to design proper and safe controllers.
- The kinematical and dynamical models of the UHP robot have been identified.
- The UHP is an innovative multipurpose rehabilitation robot for upper limbs.
- Several experimental test have been carried out to validate the identified models.
- Results show that the models can be used for force and motion estimation.
Kinematical and dynamical modelling of a multipurpose upper limbs rehabilitation robot

Abstract

Knowing accurate model of a system is always beneficial to design a robust and safe control while allowing reduction of sensors-related cost as the system outputs are predictable using the model. In this context, this paper addresses the kinematical and dynamical model identification of the multipurpose rehabilitation robot, Universal Haptic Pantograph (UHP), and present experimental validations of the identified models. The UHP is a pantograph based innovative robot actuated by two SEAs (Series Elastic Actuator), aiming at training impaired upper limbs after a stroke. This novel robot, thanks to its lockable/unlockable joints, can change its mechanical structure so that it enables stroke patient to perform different training exercises of the shoulder, elbow and wrist. This work focuses on the ARM mode, which is a training mode used to rehabilitate elbow and shoulder. The kinematical model of UHP is identified based on the loop vector equations, while the dynamical model is derived based on the Lagrangian formulation. To demonstrate the accuracy of the models, several experimental tests were performed. The results reveal that the mean position error between estimated values with the model and actual measured values stays in 3 mm (less than 2\% of the maximum motion range). Moreover,
the error between estimated and measured interaction force is smaller than 10% of maximum force range. So, the developed models can be adopted to estimate motion and force of UHP as well as control it without the need of additional sensors such as a force sensor, resulting in the reduction of total robot cost.

1. Introduction

According to the World Health Organization (WHO), every year, more than 15 million strokes or cerebrovascular accidents are diagnosed and two thirds among them survive but have to live with the sequels of stroke. Nowadays, more than 33 million people in the world are affected by stroke sequels [1, 2]. Up to date, various research results on stroke have demonstrated that, thanks to brain plasticity, stroke patients may recover most of their skills executing adequate rehabilitation exercises [3]. However, in classical rehabilitation programs, stroke patients require constant supervision by the therapist, which increases the economic cost of the therapy, and leads to the reduction of rehabilitation times, impeding continuous and long-term rehabilitation interventions [4].

Hence, over the last couple of decades, several rehabilitation robotic devices for stroke patients, particularly for upper limbs rehabilitation, have been developed [5, 6] and demonstrated at both academical and clinical settings. The robots are believed to be a good alternative to traditional rehabilitation therapies due to several advantages of the robot-mediated therapy [7]: 1) robots emulate and replicate the movements produced by a physiotherapist, executing longer duration, higher frequency and better accuracy treatments; 2) with the objective of evaluating the progress of the patient as well as adapting the exercises to their needs, the device can act as a measurement tool that quantifies forces and/or movements; 3) using a graphical interface, a virtual reality environment can be built, facilitating patient involvement in the rehabilitation process.
The rehabilitation robotic devices can be classified into two groups: end-effector type and wearable type (exoskeleton). The MIT-Manus [8], MIME [9], GENTLE/s [10], REHAROB [11] belong to the end-effector type while Armin [12], L-Exos [13], RUPERT [14] or Limpact [15] fall into the wearable type. Differently from other robotics areas where the usual position control strategies are used with great success, rehabilitation robots should take into account the interaction between the patient and the robot, and use it so as to safely apply assistive force to the patient during trainings. This indicates that it is necessary to implement advanced control algorithms that combine motion and force measurements [16]. In the literature, several approaches such as force control [17], computed torque control [18], algorithms using EMG signals [19] or neuro-fuzzy control [20] have been proposed to control the patient-robot interaction. Among the proposed approaches, impedance control introduced by Hogan in 1984 [21], and its complimentary method, admittance control, have been the most common [22, 23].

In order to implement these advanced controllers, an appropriate kinematical and dynamical model of the robot is required. This model determines the human-robot interaction forces and its motion, and force transmission between the actuators and the interaction point [24, 25]. Moreover, in order to implement the control law, the actual position and force exerted to the patient need to be not only motorized but also sensorised continuously. However, direct force measurement requires force sensors that add mechanical and electrical complexity to the mechanical structure. In addition, these sensors are normally very expensive compared to other components such as motor [26], resulting in unaffordable price of robots. Such unaffordability is one of main barriers that impede wide use of the rehabilitation robots.

Accurate models of the robot can be used to implement estimators of both position and force as an alternative of direct measurement using the sensors in order to reduce the cost of the robot. Normally, these estimators use the easily measurable variables and elements information provided by manufactures (e.g. actuator specifications) to estimate the motion and forces of the robots [27, 28].
Therefore, a proper and accurate mathematical model of the robot not only facilitates the design of the advanced control strategies but also possibly realizes affordable robotic solutions for rehabilitation area. In this context, this study presents the kinematical and dynamical modelling approach and the resultant models of a multipurpose upper limb rehabilitation robot, referred to as the Universal Haptic Pantograph (UHP) [29]. The UHP is a pantograph-based innovative device actuated by two SEAs (Series Elastic Actuator) whose main characteristic is the reconfigurability of its mechanical structure using lockable/unlockable joints. This feature allows to adapt the structure to the rehabilitation needs of different parts of the upper limb [30].

The article is organized as follows. In Section 2 the UHP rehabilitation robot and the adopted modelling approach are presented. In Section 3, as a first subsystem of UHP, the SEA based drive system and its kinematical and dynamical models are identified. Section 4 describes the identification procedure of the kinematical and dynamical models of the Pantograph which is a subsystem directly contacting users upper limbs. In Section 5, several experimental case studies are presented in order to validate the models. Finally, the most important ideas and conclusions appear in Section 6.

2. Universal Haptic Pantograph and the modelling approach

The Universal Haptic Pantograph (UHP) (Fig. 1) is a rehabilitation robot developed to train impaired upper limbs after a stroke [29]. One of the most important benefits of the UHP is its reconfigurability, which allows to modify its mechanical structure thanks to its lockable / unlockable joints. In this way, for each mechanical configuration, the UHP can execute different types of exercises that focus on certain parts of the upper limb: the shoulder, elbow and wrist [30].

This work focuses in one of the most complete modes, the ARM mode. This mode is used to rehabilitate elbow and shoulder by means of 2 degrees of freedom (DOF) motions that allow arm extension in forward, backward, leftward and
rightward directions.

In order to provide this movement, a pantograph-based structure is used to interact with the patient. The Pantograph is actuated by two perpendicular SEAs (Series Elastic Actuator) in order to generate forces in \( x \) and \( y \) directions as shown in ‘SEA based drive system’ block in Fig. 1.

![Figure 1: Universal Haptic Pantograph (UHP).](image)

The motion of the UHP results from the forces \( (F_{\text{Cn}}) \) exerted by the user in the contact point \( (P_{\text{Cn}}) \) and the torques \( (\tau_{\text{m}}) \) exerted by the motors through the SEA based drive system. The two subsystems are connected in the transmission point \( (P_{\text{Tr}}) \) such that the torque \( (\tau_{\text{m}}) \) exerted by the actuators of the drive system and the force \( (F_{\text{Cn}}) \) and motion \( (P_{\text{Cn}}) \) applied to the Pantograph by the patient are transmitted bilaterally in the form of force \( (F_{\text{Tr}}) \) and motion \( (P_{\text{Tr}}) \) (Fig. 1).
As mentioned previously, a proper mathematical model of the robot is required to implement the robot-patient force interaction controller. Since the model demands position measurements of the drive system for the estimation of the torque ($\tau_m$), the force ($F_{Cn}$) and motion ($P_{Cn}$) shown in Fig. 2, the UHP prototype includes two optical encoders and two linear potentiometers to measure the actuators rotation angle ($q_m$) and the lengths of SEAs upper springs ($n_{SA}$ and $n_{SB}$) respectively.

The inputs and outputs of the model are detailed in Fig. 2. The model of the SEA based drive system is used to compute the actuators torque ($\tau_m$) in the force controller as well as to estimate the force ($F_{Tr}$) and motion ($P_{Tr}$) of the transmission point. The Pantograph model, on the other hand, estimates the force ($F_{Cn}$) and motion ($P_{Cn}$) applied by the patient. Both models will be detailed in Sections 3 and 4 respectively.

Figure 2: UHP model subsystems.

3. Modelling of SEA based drive system

The UHP drive system is composed of two perpendicular SEAs [29, 31] and each SEA consists of an electrical actuator and a spring that makes the interface between the actuator and the load flexible, thus allows more accurate and stable force control [32]. Due to these advantages, SEAs have been often used in human-robot interaction devices [33].
The SEAs used in the UHP are composed of two Maxon RE40 rotary motors \((m_1 \text{ and } m_2)\) with integrated encoders, four elastic springs \((S_A, S_B, S_C \text{ and } S_D)\) and actuated \((p_1)\) and unactuated \((p_2)\) pulleys as shown in Fig. 3. \(P_{Tr}\), a point where SEA based drive system is connected to the Pantograph, is referred to as the transmission point and expressed by \(P_{Tr} = [x_{Tr}, y_{Tr}, z_{Tr}]^T\) (Fig. 3).

The force and motion transmission from the electric motors \((m_1 \text{ or } m_2)\) to the springs \((S_A \text{ and } S_C \text{ or } S_B \text{ and } S_D)\) and the transmission point \(P_{Tr}\) is carried out by cables. The SEAs are aligned with \(x\) and \(y\) axes (Fig. 3). By this configuration, the torque \((\tau_{m_1})\) exerted by motor \(m_1\) is transmitted to springs \(S_A\) and \(S_C\) and accordingly its force \((F_{S_A} \text{ and } F_{S_C})\) are transmitted to the transmission point \(P_{Tr}\), resulting in the movement \((x_{Tr})\) in the \(x\) axis. In a similar way, the \(y\) directional motion \((y_{Tr})\) is generated by the SEA involving motor \(m_2\) and springs \(S_B\) and \(S_D\).

The parameters used to define the geometry of the SEA drive system are detailed next. \(l_1\) is the distance from the equilibrium point of the transmission point \(P_0 = P_{Tr}\) when \(x_{Tr} = y_{Tr} = z_{Tr} = 0\) to the center of the actuated pulleys \((p_1)\). \(l_2\) is the distance between \(P_0\) and the center of the unactuated pulleys.

Figure 3: Detailed 3D Structure of SEA based drive system in UHP.
(p2) (Fig. 3). In Fig 5, it can be observed that $l_i$ is a length vector between $P_i$ and the transmission point ($P_{Tr}$) to $i = A; B; C; D$. $l_{0i}$ is the initial length of the spring $S_i$. The passive joint variables, $q_{na} = [\beta_A \beta_B \beta_C \beta_D \delta_A \delta_B \delta_C \delta_D]^T$, are the angles required to describe the direction and orientation of the cables composing the drive system.

The role of the drive system is to exert the appropriate force to the Panto-graph such that the transmitted force ($F_{Tr}$) tracks the desired one. The force $F_{Tr}$ depends on the variable length of the springs ($n_S = [n_{SA} n_{SB} n_{SC} n_{SD}]^T$), the dependent variables ($q_{na} = [\beta_A \beta_B \beta_C \beta_D \delta_A \delta_B \delta_C \delta_D]^T$), and the torque exerted by the motors ($\tau_m = [\tau_{m1} \tau_{m2}]^T$) (Figs. 3 and 5).

The relationship between the aforementioned variables will be formulated through three steps as highlighted in Fig. 4. First, the kinematical model of elastic components in SEA will be calculated in Section 3.1. Second, motor dynamics will be analyzed to obtain the relationship between their rotation angles ($q_m$) and the exerted motor torques ($\tau_m$) in Section 3.2. Finally, transmission point dynamics will be identified to calculate the transmission force ($F_{Tr}$) in Section 3.3.

Figure 4: Block diagram of sub-models composing the SEA based drive system.
Figure 5: Schematic views of elastic elements and their configuration used in SEAs: (a) the projected view of $x$ directional elastic components of SEAs in $xy$-$z$ plane, (b) the projected view of $x$ and $y$ directional elastic components in $x$-$y$ plane, (c) the projected view of $y$ directional elastic components of SEA in $xy$-$z$ plane.
3.1. Kinematical model of elastic components in SEA

To derive the kinematical model of SEA based drive system, spring variable lengths ($n_S$) (Sections 3.1.1 and 3.1.2) and the values of the dependent variables ($q_{na}$) (Sections 3.1.3) will be calculated in terms of the rotation angles of the motors ($q_m$) (Fig. 4).

3.1.1. Upper springs kinematical model

If linear springs are considered, the force exerted by each spring is proportional to the linear deformation, i.e., the variable length of the spring ($n_S$). In the UHP, springs $S_A$ and $S_B$ are sensorized using linear potentiometers, while springs $S_C$ and $S_D$ are not sensorized.

Figs. 3 and 5 show that $n_{SA}$ and $n_{SB}$ depend on the rotation angle of the motors ($q_m$) and the motion of the transmission point ($P_{Tr}$). Hence, to obtain $n_{SC}$ and $n_{SD}$, first $P_{Tr}$ needs to be calculated. To this end, in this section, the $P_{Tr}$ is formulated in terms of the rotary angles of the motors $q_m$ and the upper spring lengths $n_{SA}$ and $n_{SB}$.

If stiff and undeformable cables are considered, from Fig. 5, the vectorial equation system that determines the upper cable length vectors ($l_A$ and $l_B$) in terms of the transmission motion ($P_{Tr} = [x_{Tr} y_{Tr} z_{Tr}]^T$) and the position of $P_A = [x_A 0 z_A]^T$ and $P_B = [0 y_B z_B]^T$ is obtained,

\[
l_A + P_A - P_{Tr} = 0 \rightarrow l_A = \begin{bmatrix} x_{Tr} \\ y_{Tr} \\ z_{Tr} \end{bmatrix} - \begin{bmatrix} x_A \\ 0 \\ z_A \end{bmatrix}
\]

\[
l_B + P_B - P_{Tr} = 0 \rightarrow l_B = \begin{bmatrix} x_{Tr} \\ y_{Tr} \\ z_{Tr} \end{bmatrix} - \begin{bmatrix} 0 \\ y_B \\ z_B \end{bmatrix}
\]

From Eq. 1, the relationship between the upper cable lengths $l_A$ and $l_B$ and the transmission point displacement $P_{Tr} = [x_{Tr} y_{Tr} z_{Tr}]^T$ can be formulated
by,

\[ l_A = |l_A| = \sqrt{(x_{Tr} - x_A)^2 + y_{Tr}^2 + (z_{Tr} - z_A)^2} \]
\[ l_B = |l_B| = \sqrt{x_{Tr}^2 + (y_{Tr} - y_B)^2 + (z_{Tr} - z_B)^2} \]  \hspace{1cm} (2)

On the other hand, from Fig. 5 the relationship between the upper cable length \( l_A \) and \( l_B \) and the measurable upper spring lengths \( n_{SA} \) and \( n_{SB} \) can be defined in terms of the rotation angle of each motor \( q_{mi} \).

\[ n_{SA} = l_A + (q_{m1} - \theta_A) r_{p1} - l_1 \]
\[ n_{SB} = l_B + (q_{m2} - \theta_B) r_{p1} - l_1 \]  \hspace{1cm} (3)

where \( l_1 \) is the distance from the equilibrium point \( P_0 \) to actuated pulley \( p_1 \), \( r_{p1} \) is the radius of actuated pulleys, and the \( \theta_A \) and \( \theta_B \), which are angles depicted in Figs. 6 and 7, are derived as,

\[ \theta_A = \arctan \left( \frac{x_A}{z_A + r_{p1}} \right) \]
\[ \theta_B = \arctan \left( \frac{y_B - l_1}{z_B + r_{p1}} \right) \]  \hspace{1cm} (4)

Therefore, combining Eqs. 2 and 3 yields

\[ n_{SA} - q_{m1} r_{p1} = \sqrt{(x_{Tr} - x_A)^2 + y_{Tr}^2 + (z_{Tr} - z_A)^2 - \theta_A r_{p1} - l_1} \]
\[ n_{SB} - q_{m2} r_{p1} = \sqrt{x_{Tr}^2 + (y_{Tr} - y_B)^2 + (z_{Tr} - z_B)^2 - \theta_B r_{p1} - l_1} \]  \hspace{1cm} (5)

In order to solve Eq. 5, the position vectors of points \( P_A \) \( ([x_A \ 0 \ z_A]^T) \) and \( P_B \) \( ([0 \ y_B \ z_B]^T) \) are required. Applying the Pythagorean theorem to the actuated pulley \( p_1 \) in the \( xz \) plane (Fig. 6) leads to

\[ (x_A + l_1)^2 + (z_A + r_{p1})^2 = r_{p1}^2 \]  \hspace{1cm} (6)

On the other hand, vector \( r_1 \) and the \( xz \) plane projection of \( l_A \) \( (l_{Axz}) \) are normal, that is,

\[ r_1 \cdot l_{Axz} = 0 \rightarrow (x_A + l_1)(x_{Tr} - x_A) + (z_A + r_{p1})(z_{Tr} - z_A) = 0 \]  \hspace{1cm} (7)
Figure 6: Relation between $P_i$ ($i = A$ and $C$) and kinematical parameters of the $x$-directional SEA in Fig. 5.

Figure 7: Relation between $P_i$ ($i = B$ and $D$) and kinematical parameters of the $y$-directional SEA in Fig. 5.
Performing the same process to point $P_B$ (Fig. 7),

$$(y_B - l_1)^2 + (z_B + r_{p1})^2 = r_{p1}^2$$

$$(y_B - l_1)(y_{Tr} - y_B) + (z_B + r_{p1})(z_{Tr} - z_B) = 0$$

(8)

Combining Eqs. 5 to 8 leads to two equations that relate the transmission point ($P_{Tr}$) and the measurable variables ($q_m$, $n_{SA}$ and $n_{SB}$). However, as $P_{Tr}$ has three variables ($x_{Tr}$, $y_{Tr}$ and $z_{Tr}$), a third equation is required to solve the $P_{Tr}$. The third equation can be obtained by analyzing the motion of the Pantograph actuated bar. The actuated bar presents a spherical joint $P_E$ with respect to the Fixed structure (Fig. 3). Thus, the motion of $P_{Tr}$ is constrained to the surface of a sphere of radius $l_3$,

$$x_{Tr}^2 + y_{Tr}^2 + (l_3 - z_{Tr})^2 = l_3^2$$

(9)

which is the third equation to solve the $P_{Tr}$.

3.1.2. Lower springs kinematical model

After solving the $P_{Tr}$, the estimation of lengths $n_{SC}$ and $n_{SD}$ based on the measurable variables is required according to the procedure presented in Fig. 4. For that purpose, a similar procedure as that employed in the previous section is applied. From Fig. 5,

$$P_C + l_C - P_{Tr} = 0 \rightarrow l_C = \begin{bmatrix} x_{Tr} \\ y_{Tr} \\ z_{Tr} \end{bmatrix} - \begin{bmatrix} x_C \\ 0 \\ z_C \end{bmatrix}$$

$$P_D + l_D - P_{Tr} = 0 \rightarrow l_D = \begin{bmatrix} x_{Tr} \\ y_{Tr} \\ z_{Tr} \end{bmatrix} + \begin{bmatrix} 0 \\ y_D \\ z_D \end{bmatrix}$$

(10)

where $[x_C \ 0 \ z_C]^T$ and $[0 \ y_D \ z_D]^T$ are positions of $P_C$ and $P_D$ respectively.

The norm associated to each vector is,

$$l_C = |l_C| = \sqrt{(x_{Tr} - x_C)^2 + y_{Tr}^2 + (z_{Tr} - z_C)^2}$$

$$l_D = |l_D| = \sqrt{x_{Tr}^2 + (y_{Tr} + y_D)^2 + (z_{Tr} + z_D)^2}$$

(11)
To determine the position of the point $P_C$, the Pythagorean theorem is applied to the unactuated pulley $p_2$ (Fig. 6), which is contained in the $xz$ plane,

$$\left(x_C - l_2\right)^2 + \left(z_C + r_{p_2}\right)^2 = r_{p_2}^2 \tag{12}$$

where $l_2$ is the distance from the equilibrium point ($P_0$) to the unactuated pulleys ($p_2$) and $r_{p_2}$ is the pulleys radius.

On the other hand, vector $r_2$ and the $xz$ plane projection of $l_C$ ($l_{C_{xz}}$) are normal (Fig. 6), that is, 

$$r_2 \cdot l_{C_{xz}} = 0 \rightarrow (x_C - l_2)(x_{Tr} - x_C) + (z_C + r_{p_2})(z_{Tr} - z_C) = 0 \tag{13}$$

Performing the same process to point $P_D$ (Fig. 7),

$$\left(y_D + l_2\right)^2 + \left(z_D + r_{p_2}\right)^2 = r_{p_2}^2$$

$$\left(y_D + l_2\right)(y_{Tr} - y_D) + (z_D + r_{p_2})(z_{Tr} - z_D) = 0 \tag{14}$$

Therefore, by solving Eqs. 12 - 14 and inserting $P_C = [x_C \ 0 \ z_C]^T$ and $P_D = [0 \ y_D \ z_D]^T$ in Eq. 11, $l_C$ and $l_D$ are calculated.

So, the variable length of unsensorized springs are (Fig. 5),

$$n_{S_C} = l_C - q_{m_1} r_{p_1} + \theta_C r_{p_2} - l_2$$

$$n_{S_D} = l_D - q_{m_2} r_{p_1} + \theta_D r_{p_2} - l_2 \tag{15}$$

where from Figs. 6 and 7,

$$\theta_C = \arctan\left(\frac{x_C - l_2}{z_C + r_{p_2}}\right)$$

$$\theta_D = \arctan\left(\frac{y_D + l_2}{z_D + r_{p_2}}\right) \tag{16}$$

3.1.3. Determination of dependent variables in the model

As described in Fig. 4, after formulating the springs variable length ($n_S$) and the position of the $P_{Tr}$, it is required to compute the dependent variables ($q_{naS} = [\beta_A \ \beta_B \ \beta_C \ \beta_D \ \delta_A \ \delta_B \ \delta_C \ \delta_D]^T$) to complete kinematical model of the drive system.
As it can be seen in Fig. 5, $\beta_i$ is the angle between axes $x$ and $y$, and $\delta_i$ is the angle between axis $z$ and plane $xy$ that defines the direction of $l_i$ to $i = A; B; C; D$. By applying trigonometry, the following relationships are obtained:

$$
\beta_A = \arctan\left(\frac{y_{Tr}}{x_{Tr} - x_A}\right)
$$

$$
\beta_B = \arctan\left(\frac{x_{Tr}}{y_{Tr} - y_B}\right)
$$

$$
\beta_C = \arctan\left(\frac{y_{Tr}}{x_C - x_{Tr}}\right)
$$

$$
\beta_D = \arctan\left(\frac{x_{Tr}}{y_{Tr} - y_D}\right)
$$

$$
\delta_A = \arctan\left(\frac{z_{Tr} - z_A}{\sqrt{(x_{Tr} - x_A)^2 + y_{Tr}^2}}\right)
$$

$$
\delta_B = \arctan\left(\frac{z_{Tr} - z_B}{\sqrt{x_{Tr}^2 + (y_B - y_{Tr})^2}}\right)
$$

$$
\delta_C = \arctan\left(\frac{z_{Tr} - z_C}{\sqrt{(x_C - x_{Tr})^2 + y_{Tr}^2}}\right)
$$

$$
\delta_D = \arctan\left(\frac{z_{Tr} - z_D}{\sqrt{x_{Tr}^2 + (y_{Tr} - y_D)^2}}\right)
$$

### 3.2. Dynamical model of the actuators

Once the variable lengths ($n_S$) of the springs and the dependent variables ($q_{\text{max}}$) are calculated, the dynamical model of the motor can be obtained (Fig. 4).

The actuation torque exerted by each motor $j = 1; 2$ ($\tau_{m_j}$) is calculated as,

$$
\tau_{m_j} - \tau_{S_j} = I_{m_j} \ddot{q}_{m_j} + B_{m_j} \dot{q}_{m_j} + F_{c_j} \tanh(\beta_j \dot{q}_{m_j})
$$

where $I_{m_j}$ is the inertia, $B_{m_j}$ the torsional viscous friction coefficient and $F_{c_j}$ and $\beta_j$ the Coulomb friction [34]. $\tau_{S_1} = \tau_{S_A} + \tau_{S_C}$ and $\tau_{S_2} = \tau_{S_B} + \tau_{S_D}$ define the equivalent torques exerted by the springs in each motor $j = 1; 2$. This torque is calculated by multiplying the force exerted by each spring ($F_{m_i}$) by the radius
of the actuated pulley \((r_{p1})\) (Figs. 8 and 9). As motor \(m_1\) is contained in plane \(xz\) and motor \(m_2\) in plane \(yz\),

\[
\tau_{S1} = \tau_{SA} + \tau_{SC} = \begin{bmatrix} F_{SA_{xz}} \end{bmatrix}_{r_{p1}} + \begin{bmatrix} F_{SC_{xz}} \end{bmatrix}_{r_{p1}}
\]

\[
\tau_{S2} = \tau_{SB} + \tau_{SD} = \begin{bmatrix} F_{SB_{yz}} \end{bmatrix}_{r_{p1}} + \begin{bmatrix} F_{SD_{yz}} \end{bmatrix}_{r_{p1}}
\]

(20)

On the other hand, the magnitude of each spring force \((F_{Si})\) depends on its variable length \((n_{Si})\) and its constant \((k_{Si})\), while its direction \((u_i)\) depends on the passive variables \((q_{na})\),

\[
F_{Si}^{m}(n_{Si}, q_{na}) = F_{S}, u_i = k_{Si}, n_{Si}, u_i
\]

(21)

where the unitary force direction vectors \(u_i\) are (Figs. 5 and 9),

\[
u_A = \begin{bmatrix} \cos \beta_A \cos \delta_A & \sin \beta_A \cos \delta_A & \sin \delta_A \end{bmatrix}^T
\]

\[
u_B = \begin{bmatrix} \sin \beta_B \cos \delta_B & -\cos \beta_B \cos \delta_B & \sin \delta_B \end{bmatrix}^T
\]

\[
u_C = \begin{bmatrix} -1 & 0 & 0 \end{bmatrix}^T
\]

\[
u_D = \begin{bmatrix} 0 & 1 & 0 \end{bmatrix}^T
\]

(22)

Figure 8: Representation of forces and torques resulting from the springs and motors in SEA based drive system.
So, the torques exerted by the springs in each motor are,
\[ \tau_{S1} = \tau_{SA} + \tau_{SC} = k_{SA} n_{SA} r_{p1} \sqrt{\cos^2 \delta_A \cos^2 \delta_A + \sin^2 \delta_A} + k_{SC} n_{SC} r_{p1} \]
\[ \tau_{S2} = \tau_{SB} + \tau_{SD} = k_{SB} n_{SB} r_{p1} \sqrt{\cos^2 \delta_B \cos^2 \delta_B + \sin^2 \delta_B} + k_{SD} n_{SD} r_{p1} \]  \hspace{1cm} (23)

3.3. Dynamical model of the drive system: dynamics of Transmission Point

As a final step in modelling of SEA based drive system, dynamics of the transmission point is identified (Fig. 4). The transmission point \( P_{Tr} \) defines the contact point between the Pantograph and the drive system. As the drive system is based on a motor-spring actuation, the exerted force (\( F_{Tr} \)) is calculated based on the spring forces that are transmitted through the cables (\( F_{TrSi}^{F_S} \)) (Figs. 8 and 10),
\[ F_{Tr} = \sum_{i=A}^{D} F_{TrSi}^{F_S} = F_{TrSA}^{F_S} + F_{TrSB}^{F_S} + F_{TrSC}^{F_S} + F_{TrSD}^{F_S} \]  \hspace{1cm} (24)

The magnitude of each spring force (\( F_{Si} \)) depends on its variable length (\( n_{Si} \)) and its constant (\( k_{Si} \)), while its direction (\( \mathbf{v}_1 \)) depends on the passive variables (\( \mathbf{q}_{nas} \)),
\[ F_{TrSi}^{F_S}(n_{Si}, \mathbf{q}_{nas}) = k_{Si} n_{Si} \mathbf{v}_1 \]  \hspace{1cm} (25)
Figure 10: Resultant force \( (F_{Tr}) \) at Transmission point \( (P_{Tr}) \).

where \( v_i \) is the unitary direction vector of \( l_i \) to \( i = A; B; C; D \), which depends on \( q_{naS} = [\beta_A \beta_B \beta_C \beta_D \delta_A \delta_B \delta_C \delta_D]^T \) (Figs. 5 and 10),

\[

v_A = \begin{bmatrix}
-\cos \beta_A \cos \delta_A \\
-\sin \beta_A \cos \delta_A \\
-\sin \delta_A 
\end{bmatrix}^T
\]

\[

v_B = \begin{bmatrix}
-\sin \beta_B \cos \delta_B \\
-\sin \beta_B \cos \delta_B \\
-\sin \delta_B 
\end{bmatrix}^T
\]

\[

v_C = \begin{bmatrix}
-\cos \beta_C \cos \delta_C \\
-\sin \beta_C \cos \delta_C \\
-\sin \delta_C 
\end{bmatrix}^T
\]

\[

v_D = \begin{bmatrix}
\sin \beta_D \cos \delta_D \\
\cos \beta_D \cos \delta_D \\
\sin \delta_D 
\end{bmatrix}^T
\]

(26)

So, the transmission force \( (F_{Tr}) \) in terms of the variable length \( (nS) \) of the springs and the dependent variables \( (q_{nas}) \) is given by,

\[

F_{Tr} = k_{SA} n_{SA} \begin{bmatrix}
-\cos \beta_A \cos \delta_A \\
-\sin \beta_A \cos \delta_A \\
-\sin \delta_A 
\end{bmatrix} + k_{SB} n_{SB} \begin{bmatrix}
-\sin \beta_B \cos \delta_B \\
\cos \beta_B \cos \delta_B \\
-\sin \delta_B 
\end{bmatrix} + k_{SC} n_{SC} \begin{bmatrix}
-\cos \beta_C \cos \delta_C \\
\sin \beta_C \cos \delta_C \\
\sin \delta_C 
\end{bmatrix} + k_{SD} n_{SD} \begin{bmatrix}
\sin \beta_D \cos \delta_D \\
\cos \beta_D \cos \delta_D \\
\sin \delta_D 
\end{bmatrix} + k_{SD} n_{SD} \begin{bmatrix}
\sin \beta_D \cos \delta_D \\
\cos \beta_D \cos \delta_D \\
\sin \delta_D 
\end{bmatrix}
\]

(27)
4. Modelling of Pantograph structure

The Pantograph is the part of the UHP rehabilitation robot which interacts with the patient. It is composed of three mobile bars (actuated, transverse and parallel) and a fixed structure [30] (Fig. 11). Moreover, these bars can be represented by five mobile elements ($E_1$, $E_2$, $E_3$, $E_4$ and $E_5$) and five joints ($P_E$, $P_F$, $P_G$, $P_H$ and $P_I$), where joints $P_F$, $P_H$ and $P_I$ are lockable/unlockable. This mechanical structure allows 2 DoFs motion, depending on the combination of joints $P_F$, $P_H$ and $P_I$.

![Figure 11: Pantograph in ARM mode.](image)

In ARM mode, as the joint $P_F$ is locked, relative motion between elements $E_2$ and $E_3$ does not happen. Furthermore, revolute joint $P_H$ and universal joint $P_I$ are unlocked, in order to allow the motion of the parallel and transverse bars. As a result, a four-bar mechanism structure is defined, where all the bars are always contained in plane $\pi$ while allowing rotation ($\alpha$) about $y$ axis (Fig. 11). Similarly, the four-bar mechanism allows motion in the direction of the $y$ axis.
of π plane, which is defined by the variation of the angles of the actuated (ϕ₁), parallel (ϕ₂) and transverse (ϕ₃) bars with respect to the xz plane.

Therefore, when the drive system applies force at the lower end of the actuated bar (P_{Tr}), this generates movement of both parallel and transverse bars and consequently moves the patient's arm attached to Pantograph. The resulting motion in ARM mode is 2 DoFs in x and y directions.

Moreover, thanks to the slider that allows relative translation between elements E₁ and E₂, the actuated bar length can vary. In this way, the transverse bar inclination can be modified to achieve an ergonomical position for the patient (Fig. 11). During the execution of the training exercise, the variable length d₁ is locked in a known position to prevent undesirable changes in its length for the safety (Fig. 12).

Figure 12: Representation of parameters describing the Pantograph configuration.

In the particular case where the variable length d₁ is zero (Fig. 12), the parallel bar and the actuated bar have the same length. Hence, the structure is
a regular four-bar mechanism, in which both pairs of bars, parallel and actuated and transverse and fixed are always parallel ($\varphi_1 = \varphi_2, \varphi_3 = 0$).

The equilibrium position of the UHP is achieved when the actuated bar is in vertical position ($\varphi_1 = 0$ and $\alpha = 0$), defining the origin of the base reference frame $P_0 = P_{Tr}$ ($x_{Tr} = y_{Tr} = z_{Tr} = 0$).

On the other hand, the rest of the parameters that are used to define the geometry of the Pantograph are detailed in Fig. 12.

With the aim of identifying the relationship between the contact ($P_{Cn}$) and transmission ($P_{Tr}$) points, the kinematical (Section 4.1) and dynamical (Section 4.2) models of the Pantograph in ARM mode are derived (Fig. 2).

### 4.1. Kinematical model

First, the Pantograph kinematical model, that relates the motion of the transmission point $P_{Tr} = [x_{Tr} y_{Tr} z_{Tr}]^T$, and the contact point position $P_{Cn} = [x_{Cn} y_{Cn} z_{Cn}]^T$ are calculated based on the kinematical loop equation (Fig. 12),

$$P_{Tr} + l_5 + d_1 + l_7 - P_{Cn} = 0 \quad (28)$$

Solving for $P_{Cn}$,

$$
\begin{bmatrix}
  x_{Cn} \\
  y_{Cn} \\
  z_{Cn}
\end{bmatrix} =
\begin{bmatrix}
  x_{Tr} \\
  y_{Tr} \\
  z_{Tr}
\end{bmatrix} + \frac{l_5 + d_1 + l_7}{l_3}
\begin{bmatrix}
  -x_{Tr} \\
  -y_{Tr} \\
  l_3 - z_{Tr}
\end{bmatrix}
\begin{bmatrix}
  -l_4 - d_1 - l_7 \\
  l_3
\end{bmatrix}
\begin{bmatrix}
  x_{Tr} \\
  y_{Tr} \\
  z_{Tr}
\end{bmatrix}
\begin{bmatrix}
  x_{Tr} \\
  y_{Tr} \\
  z_{Tr}
\end{bmatrix}
\begin{bmatrix}
  0 \\
  0 \\
  l_5 + d_1 + l_7
\end{bmatrix}
\quad (29)
$$

Eq. 29 relates the input ($P_{Tr}$) and output ($P_{Cn}$) motion, but in order to fully define the motion of the Pantograph, the position of point $P_{H}$ must be calculated. For this purpose, a geometrical approach based on the intersection of circumferences is used.
In ARM mode, the bars composing the Pantograph are always contained in the \( \pi \) plane, which can rotate \( \alpha \) around \( y \) axis (Fig. 11). Hence, considering that the Pantograph behaves as a four-bar mechanism, its kinematics can be calculated by defining two circumferences of center in joints \( P_G \) and \( P_I \), and constant radius \( l_8 \) and \( l_9 \), respectively (Fig. 13). To calculate the intersection \( P_H \), the coordinates of \( P_G \) and \( P_I \) have to be projected to the plane. To perform this projection the reference system is moved to point \( P_E \) and the axes \( y^\pi \) and \( w^\pi \) are taken as coordinates, where \( y^\pi = y \) and \( w^\pi = \sqrt{x^2 + (l_3 - z)^2} \).

![Figure 13: Pantograph projection on the plane \( \pi \).](image)

The position of the circumferences center (\( P_G \) and \( P_I \)) in the reference system of the UHP \((x, y, z)\) are (Fig. 13),

\[
P_G = P_{Tr} + l_3 + l_4 + d_1 + l_6 = \frac{l_4 + d_1 + l_6}{l_3} \begin{bmatrix} -x_{Tr} \\ -y_{Tr} \\ -z_{Tr} + l_3 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ l_3 \end{bmatrix}
\]
\[ P_1 = P_{Tr} + l_3 - l_{10} = \begin{bmatrix} 0 \\ l_{10} \\ l_3 \end{bmatrix} \]  

So, their projection on the plane \( \pi \) (\( P_{G\pi} \) and \( P_{I\pi} \)),

\[
P_{G\pi} = \frac{(l_4 + d_1 + l_6)}{l_3} \begin{bmatrix} -y_{Tr} \\ \sqrt{x_{Tr}^2 + (l_3 - z_{Tr})^2} \end{bmatrix}
\]

\[
P_{I\pi} = \begin{bmatrix} l_{10} \\ 0 \end{bmatrix}
\]

Therefore, the circumferences, defined in the \( \pi \) plane,

\[
\left( y_{H\pi} + \frac{l_4 + d_1 + l_6}{l_3} y_{Tr} \right)^2 + \left( w_{H\pi} - \frac{l_4 + d_1 + l_6}{l_3} \sqrt{x_{Tr}^2 + (l_3 - z_{Tr})^2} \right)^2 = l_8^2
\]

(32)

Solving the Eq. 32, the intersection point \( P_{H\pi} \) defined in the \( \pi \) plane coordinate system is obtained. So, its value in the reference system of the UHP \((x, y, z)\) is,

\[
x_{H} = w^\pi_{H} \sin \alpha
\]

\[
y_{H} = y^\pi_{H}
\]

\[
z_{H} = w^\pi_{H} \cos \alpha + l_3
\]

where the angle \( \alpha \) is the inclination angle of plane \( \pi \) with respect to \( xz \) plane, and is defined as,

\[
\alpha = \arctan \left( \frac{x_E - x_{Tr}}{z_E - z_{Tr}} \right) = \arctan \left( \frac{-x_{Tr}}{l_3 - z_{Tr}} \right)
\]

(34)

Once the \( \alpha \) is calculated, the rest of the passives variables that define the kinematical model of the Pantograph \((q_{\text{mna}} = [\alpha \ \varphi_1 \ \varphi_2 \ \varphi_3]^T)\) can be obtained knowing that \( y^\pi = y \) and \( w^\pi = \sqrt{x^2 + (l_3 - z)^2} \) (Figs. 11 and 13),

\[
\varphi_1 = \arctan \left( \frac{y^\pi_E - y^\pi_{Tr}}{w^\pi_E - w^\pi_{Tr}} \right) = \arctan \left( \frac{y_{Tr}}{w_{Tr}} \right)
\]

\[
= \arctan \left( \frac{y_{Tr}}{\sqrt{x_{Tr}^2 + (l_3 - z_{Tr})^2}} \right)
\]

(35)
\[ \varphi_2 = \arctan\left(\frac{y_H^H - y_I^H}{w_H^H - w_I^H}\right) = \arctan\left(\frac{y_H^H + l_{10}}{w_H^H}\right) \]
\[ = \arctan\left(\frac{y_H^H + l_{10}}{\sqrt{x_H^T + (l_3 - z_H)^2}}\right) \quad (36) \]

\[ \varphi_3 = \arctan\left(\frac{w_G^G - w_H^H}{y_G^G - y_H^H}\right) \quad (37) \]

where \( y_G^G \) and \( w_G^G \) are defined in Eq. 31, so,

\[ \varphi_3 = \arctan\left(\frac{l_3 w_H - l_4 - d_1 - l_6 \sqrt{x_T^T + (l_3 - z_T)^2}}{l_3 y_H + l_4 + d_1 + l_6 y_T}\right) \quad (38) \]

In the particular case where \( d_1 = 0 \), the actuated and the parallel bars will have an equal length, so \( w_H^H = w_G^G \), \( \varphi_3 = 0 \) and \( \varphi_1 = \varphi_2 \).

Once the position problem is defined, the speed problem of the Pantograph can be completely defined by calculating the Jacobian matrices relating the time derivatives of the output variables (\( \dot{P}_{Cn} \)) and passives variables (\( \dot{q}_{naA} \)) with the time derivative of the input variables (\( \dot{P}_{Tr} \)).

Hence, derivating Eq.29, the input-output Jacobian can be calculated,

\[ \dot{P}_{Cn} = \begin{bmatrix} J_x \end{bmatrix}_{3 \times 3} \dot{P}_{Tr} \quad (39) \]

Similarly, inserting \( P_H \) value and taking the time derivative in Eqs. 34 - 37,

\[ \dot{\alpha} = \begin{bmatrix} J_{\alpha} \end{bmatrix}_{1 \times 3} \dot{P}_{Tr} \]
\[ \dot{\varphi}_1 = \begin{bmatrix} J_{\varphi_1} \end{bmatrix}_{1 \times 3} \dot{P}_{Tr} \]
\[ \dot{\varphi}_2 = \begin{bmatrix} J_{\varphi_2} \end{bmatrix}_{1 \times 3} \dot{P}_{Tr} \quad (40) \]
\[ \dot{\varphi}_3 = \begin{bmatrix} J_{\varphi_3} \end{bmatrix}_{1 \times 3} \dot{P}_{Tr} \]
Combining Eqs. 39 and 40,

\[
\dot{q}_{naA} = \begin{bmatrix}
\dot{\alpha} \\
\dot{\varphi}_1 \\
\dot{\varphi}_2 \\
\dot{\varphi}_3
\end{bmatrix} = \begin{bmatrix}
J_{\alpha} \\
J_{\varphi_1} \\
J_{\varphi_2} \\
J_{\varphi_3}
\end{bmatrix}
\]

\[
\dot{P}_{Tr} = J_{q_{naA}} \dot{P}_{Tr} = J_{q_{naA}} J_x^{-1} \dot{P}_{Cn}
\]  

(41)

4.2. Dynamical model: dynamics of Transmission point

The dynamical model of the Pantograph is used to determine the relationship between the transmission force from the SEA (\(F_{Tr}\)) and the contact force from the patient (\(F_{Cn}\)) depending on the transmission motion (\(P_{Tr}\)). For this purpose, the Lagrangian formulation is used [35].

In ARM mode the Pantograph is composed by five elements (\(E_1, E_2, E_3, E_4\) and \(E_5\), where \(E_1, E_2, E_3\) have the same motion due to the lockable joints \(P_F\)) (Fig. 14).

Figure 14: Position of center of mass of Pantograph segments.
Therefore, the Langrangian function can be defined as,

\[ L = K_{E1} + K_{E2} + K_{E3} + K_{E4} + K_{E5} - (U_{E1} + U_{E2} + U_{E3} + U_{E4} + U_{E5}) \]  \tag{42}

where \( K_{Ei} \) and \( U_{Ei} \) are kinetic and potential energies of each element, defined as,

\[ K_{Ei} = \frac{1}{2} m_{Ei} \begin{bmatrix} v_{CM_{Ei}}^T \end{bmatrix} v_{CM_{Ei}} + \frac{1}{2} \omega_{CM_{Ei}}^T I_{Ei} \omega_{CM_{Ei}} \]  \tag{43}

\[ U_{Ei} = m_{Ei} g h_{CM_{Ei}} \]  \tag{44}

where \( m_{Ei} \) is the mass of each element, \( I_{Ei} \) its inertia, \( h_{CM_{Ei}} \) the \( z \) coordinate of the center of mass position, \( v_{CM_{Ei}} \) the linear velocity of the center of mass and \( \omega_{CM_{Ei}} \) its angular velocity. The position of the center of mass of each element \( CM_{Ei} \) is shown in Fig. 14.

\[ CM_{E1} = P_{Tr} + l_{CM_{E1}} \]
\[ CM_{E2} = P_{Tr} + l_3 + l_4 + d_1 - l_{CM_{E2}} \]
\[ CM_{E3} = P_{Tr} + l_3 + l_4 + d_1 + l_{CM_{E3}} \] \tag{45}
\[ CM_{E4} = P_{Tr} + l_3 + l_{10} + l_9 + l_{CM_{E4}} \]
\[ CM_{E5} = P_{Tr} + l_3 + l_{10} + l_{CM_{E5}} \]

The linear velocity \( (v_{CM_{Ei}}) \) is obtained by differentiating \( CM_{Ei} \),

\[ v_{CM_{Ei}} = \frac{\partial CM_{Ei}}{\partial P_{Tr}} \frac{\dot{P}_{Tr}}{} \]  \tag{46}

On the other hand, the angular velocities are calculated in terms of the passive variables,

\[ \omega_{CM_{E1}} = \begin{bmatrix} -\dot{\phi}_1 \cos(\alpha) \\ -\dot{\alpha} \\ -\dot{\phi}_1 \sin(\alpha) \end{bmatrix} \] \tag{47}

\[ \omega_{CM_{E4}} = \begin{bmatrix} -\dot{\phi}_3 \cos(\alpha) \\ -\dot{\alpha} \\ -\dot{\phi}_3 \sin(\alpha) \end{bmatrix} \]  \tag{48}
Combining Eqs. 43-49, kinetic and potential energies are defined in terms of the transmission motion \( P_{Tr} \), the dependent variables \( q_{naA} \) and their derivatives \( \dot{P}_{Tr}, \dot{q}_{naA} \). So, the Lagrangian function of the Pantograph will depend on these two sets of variables \( L(P_{Tr}, \dot{P}_{Tr}, q_{naA}, \dot{q}_{naA}) \).

Applying the Lagrangian formulation (Eq. 42),

\[
D_{Tr} \ddot{P}_{Tr} + C_{Tr} \dot{P}_{Tr} + G_{Tr} = \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{P}_{Tr}} \right) - \frac{\partial L}{\partial P_{Tr}} + \sum \lambda_{Tr} \frac{\partial \Gamma_{Tr}(P_{Tr}, q_{naA})}{\partial P_{Tr}} + F_{Tr} \quad (50)
\]

\[
D_{q} \ddot{q}_{naA} + C_{q} \dot{q}_{naA} + G_{q} = \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}_{naA}} \right) - \frac{\partial L}{\partial q_{naA}} + \sum \lambda_{Tr} \frac{\partial \Gamma_{Tr}(P_{Tr}, q_{naA})}{\partial q_{naA}} \quad (51)
\]

where, \( \Gamma_{Tr}(P_{Tr}, q_{naA}) = 0 \) is the closure equation that relates the input and output variables (Eq. 29), \( \lambda_{Tr} \) is the set of Lagrange multipliers, and \( F_{Tr} \) is the force applied in the transmission point \( P_{Tr} \). On the other hand, inertia \( D \), Coriolis \( C \) and gravity \( G \) terms, which depends on the dependant variables \( (D_{q}, C_{q} \text{ and } G_{q}) \) or transmission motion \( (D_{Tr}, C_{Tr} \text{ and } G_{Tr}) \), can be easily defined by grouping acceleration, velocity and gravitational terms.

If the model is to be defined in terms of \( P_{Tr} \), and considering that \( J_{q_{naA}} = \partial q_{naA} / \partial P_{Tr} \) (Eq. 41),

\[
F_{Tr} = D_{Tr} \ddot{P}_{Tr} + C_{Tr} \dot{P}_{Tr} + G_{Tr} + J_{q_{naA}}^{T} (D_{q} \ddot{q}_{naA} + C_{q} \dot{q}_{naA} + G_{q}) - J_{x}^{T} F_{Cn} \quad (52)
\]

which can be rewritten in compact form in terms of \( P_{Tr} \) and its velocity and acceleration,

\[
F_{Tr} = D P_{Tr}^{2} + C P_{Tr} + G + F_{E} \quad (53)
\]
where,
\[
\begin{align*}
D & = D_{Tr} + J_{q_{naA}}^T D_q J_{q_{naA}} \\
C & = C_{Tr} + J_{q_{naA}}^T C_q J_{q_{naA}} + J_{q_{naA}}^T D_q J_{q_{naA}} \\
G & = G_{Tr} + J_{q_{naA}}^T G_q \\
F_E & = -J_x^T F_{Cn}
\end{align*}
\]

Thus, the relationship between the interaction force ($F_{Cn}$) and dynamical behavior ($F_{Tr}$ and $P_{Tr}$) of the transmission point is obtained by Eq. 54.

5. Experimental Validation

Several experimental tests were carried out to demonstrate the effectiveness of the identified kinematical and dynamical models of the UHP rehabilitation robot. With this objective, the defined models were implemented in Matlab, and its results were compared with data obtained from experimental tests with the UHP prototype.

For that purpose, in addition to the sensors included in the prototype, (i.e. the encoders measuring motor rotation angle ($q_m$) and the linear potentiometers used to determine the lengths of upper springs ($n_{SA}$ and $n_{SB}$)), a force sensor (MINI40, ATI) and a 3 axis inclinometer (YNGS1, Sensor-Technik Wiedemann GmbH) were added to the actuated bar. The force sensor, which was located in the contact point ($P_{Cn}$), was used to measure the contact force ($F_{Cn}$), while the inclinometer, measuring the actuated bar inclination in $x$ and $y$ axes, allows to precisely estimate the contact point motion ($P_{Cn}$).

The motor controllers, prototype sensors and extra sensors were connected to a centralized embedded controller based on CompactRIO platform. The data acquisition system was implemented in Labview Real-Time.

The distance parameters of the UHP were experimentally identified, while the motor-pulley parameters (Eq. 19) were identified using the Grey-box procedure [34]. And the Pantograph mass and inertia were obtained from combining
real measurements and MSC ADAMS multibody simulation software. The parameters of the UHP are summarized in Table 1.

</table>

Table 1: Parameters of the UHP prototype.

Four tests were carried out to validate the kinematical and dynamical models of UHP rehabilitation robot. In order to show that the models work correctly when the robot interacts with the user, the experimental tests were performed with healthy people. It is noted that 75 experiments were carried out, and that
only the most significative results are shown to demonstrate the validity of the models.

First, the kinematical models of the drive system SEA (Section 3.1) and the Pantograph in ARM mode (Section 4.1) were validated. For this purpose, the motors executed a 5s period sinusoidal motion without external force. This means that the user did not execute any resistive force to the movement of the motors. The motor rotation angles ($q_m$) and variable length of the upper springs ($n_{SA}$ and $n_{SB}$) were used to estimate the contact motion ($P_{Cn}$). In order to validate the estimation, $P_{Cn}$ was also calculated from the inclinometer measurements.

In Fig. 15, the real and estimated values of $x$ and $y$ components ($x_{Cn}$ and $y_{Cn}$) of $P_{Cn}$ are depicted. As it can be seen, the mean error is smaller than 3mm and the maximum error is 6mm. Note that the motion area of the UHP in ARM mode is a circumference of 150mm radius, hence, the motion error is less than 2% of the motion area and the obtained kinematical model can be used to estimate the contact motion ($P_{Cn}$) without the need of additional sensors.

The second test was used to validate the dynamical model of the drive system (Section 3.2). With this objective, the Pantograph was locked in the equilibrium
position \( \mathbf{P}_{Tr} = [0 \ 0 \ 0]^T \) and the motors were induced to perform a sinusoidal motion with 5s period. The force of the sensorized upper springs \( F_{SA} \) and \( F_{SB} \) was calculated based on the motor torques \( (\tau_m) \) and rotation angles \( (\mathbf{q}_m) \). These values were compared with the forces directly computed with spring constants and their length variations measured by the linear potentiometer.

Fig. 16, shows the real and estimated values of \( F_{SA} \) and \( F_{SB} \). In this case, the mean error is 2N. The springs of the UHP present a maximum variable length \( (n_S) \) of 30mm, hence, with its constant \( (k_S) \) 4000N/m, the maximum force that can apply to each spring \( (F_S = k_S \ n_S) \) is ±120N. Therefore, the estimation error is less than 3% of the force range of the spring.

![Figure 16: Dynamical model validation results: SEA based drive system.](image)

The third experimental test was implemented to validate the transmission point \( \mathbf{P}_{Tr} \) dynamics (Section 3.3) and Pantograph dynamical model (Section 4.2). For this purpose, the motors were locked and the user moved the UHP through its motion range. The variable length of the upper springs \( (n_{SA} \text{ and } n_{SB}) \) were used to obtain the transmission force \( (\mathbf{F}_{Tr}) \) based on the drive system dynamical model (Eq. 27). This estimation was compared with the measurement of the contact force \( (\mathbf{F}_{Cn}) \) and the use of the dynamical model of the Pantograph.
Fig. 17 shows the values of $F_{Tr}$ calculated with both the dynamical models of the SEA based drive system and the Pantograph in ARM mode. As it can be observed, the mean error is smaller than 5 N. In a robust and safe robot operation, the contact point impedance of the UHP in ARM mode should be less than 400 N/m, so the contact force ($F_{Cn}$) oscillates in the range ±60 N. Considering the geometry of the Pantograph, the estimated transmission force ($F_{Tr}$) range is 3.2 times wider than the contact force ($F_{Cn}$) range so the maximum $F_{Tr}$ becomes ±192 N. Hence, the mean error is less than 3%, while the maximum error is smaller than 10% of the maximum force range.

![Figure 17: Dynamical model validation results: Pantograph structure.](image)

In the previous tests, the kinematical and dynamical models of the SEA drive system and Pantograph were validated separately under specific constrained motions of the robot. In the fourth and last test, the whole system was validated. For that purpose, the drive system was induced to perform a sinusoidal motion with 5s period, while the user tried to maintain the robot as close to the origin as possible.

For that purpose, the motor rotation angles ($q_m$) and the variable length of the upper springs ($n_{SA}$ and $n_{SB}$) were used to calculate the motion of the contact...
point \((\mathbf{P}_{\text{Cn}})\), which was compared with the actual values reconstructed with the inclinometer signals. In addition, the transmission force \(\mathbf{F}_{\text{Tr}}\) was obtained based on the drive systems model, and with the force sensors measures and the use of the dynamical model of the Pantograph.

In Fig. 18, the real and estimated values of \(\mathbf{P}_{\text{Cn}}\) are observed. As it can be extracted from the experimental data, the mean error is smaller than 3\(\text{mm}\) and the maximum error is 10\(\text{mm}\). As mentioned previously, motion area of the UHP in ARM mode is a circumference of 150\(\text{mm}\) radius, hence, the motion error is less than 3.34\% of the motion area.

![Figure 18: Kinematical validation results of UHP model.](image)

Fig. 19 shows the values of \(\mathbf{F}_{\text{Tr}}\) calculated with both the dynamical models of the SEA based drive system and the Pantograph in ARM mode. As it can be seen, the mean error is smaller than 10\% of the maximum force range.

It is noted that in health and care applications such as rehabilitation, movement accuracy is not as critical as in other applications like surgery. In the literature [36], the position resolution that healthy humans can control during upper limbs movement is 5\(\text{mm}\) in the average, indicating that the mean error of 3\(\text{mm}\) is higher than the resolution of human arm movement. Moreover, in the most of actual robot mediated trainings using force, the force magnitude is
smaller than $20N$ for the patient safety [37], which means force errors of 10% correspond to $2N$. In this sense, the position and force errors obtained in this study are likely to be acceptable in the use for rehabilitation purpose.

6. Conclusions

In this paper, kinematical and dynamical models of the multipurpose rehabilitation robot, Universal Haptic Pantograph (UHP) have been identified. This work focuses on the ARM mode which is used for impaired elbow and shoulder rehabilitation, among different rehabilitation modes offered by UHP thanks to its reconfigurable mechanical structure.

The UHP structure can be divided in two subsystems: a SEA based drive system, and a Pantograph structure with which the user interacts. These two subsystems are connected through the transmission point, allowing the control of motion and force of UHP depending on the purpose of the rehabilitation program. Based on the loop vector equations and the Lagrangian formulation, the kinematical and dynamical models of both subsystems have been derived,
aiming to estimate system outputs with the minimum of required sensors as well as facilitate the design of advanced interaction controllers between user and UHP.

In order to demonstrate the validity of the model and its application as motion and force estimators, several experimental tests were carried out. For the validation, the system outputs estimated using the models were compared with those obtained by measurements. The results demonstrate that the motion mean error in the contact point ($P_{cn}$) is less than 4% of the motion area, while the transmission force ($F_{Tr}$) error is smaller than the 10% of maximum force range. Moreover, these results imply that the models can be used in the estimation of the system outputs as well as in the design of the controller with acceptable accuracy and reliability for rehabilitation applications as the obtained accuracy is higher than human motion and force resolution. Therefore, it is concluded that the use of the developed model can minimize required sensor sets, resulting in the reduction of the robot cost.

In future works, the proposed kinematical and dynamical models will apply to the implementation of advanced controllers for rehabilitation purpose. And the control performance will be compared with that based on direct measurement of force and motion while interacting with the user.
